

# Lead Scoring Case Study Summary

## Problem Statement:

X Education sells online courses to industry professionals. X Education needs help in selecting the most promising leads, i.e. the leads that are most likely to convert into paying customers.

The company needs a model wherein a lead score is assigned to each of the leads such that the customers with higher lead score have a higher conversion chance and the customers with lower lead score have a lower conversion chance.

The CEO, in particular, has given a ballpark of the target lead conversion rate to be around 80%.

## Solution Summary:

### Step1: Reading and Understanding Data

Read and analyse the data.

### Step2: Data Cleaning and Preparation

We dropped the variables that had high percentage of NULL values in them. This step also included imputing the missing values as and where required with median values in case of numerical variables and creation of new classification variables in case of categorical variables.

### Step3: Data Analysis

In this step, there were 12 variables that were identified to have only one value, 'NO' in all rows. These variables were dropped.

### Step4: Creating Dummy Variables

We went on with creating dummy variables for the categorical variables.

### Step5: Test Train Split

The next step was to split the data set into train and test sections with a proportion of 70-30 respectively.

### Step6: Feature Rescaling

We used the Min Max Scaling to scale the original numerical variables: **TotalVisits**, **Page Views Per Visit** and **Total Time Spent on Website**.

### Step7: Feature selection using RFE

Using the Recursive Feature Elimination we went ahead and selected the 15 top important features. Using the statistics generated, we recursively tried looking at the P-values in order to select the most significant values that should be present and dropped the insignificant values. Finally, we arrived at the 11 most significant variables. The VIF's for these variables were also found to be good. We then created the data frame having the converted probability values and we had an initial assumption that a probability value of more than 0.5 means 1 else 0. Based on the above assumption, we derived the Confusion Metrics and calculated the overall Accuracy of the model. We also calculated the 'Sensitivity' and the 'Specificity' matrices to understand how reliable the model is.

**Step8: Plotting the ROC Curve**

We then tried plotting the ROC curve for the features and the curve came out to be pretty decent with an area coverage of 86%.

**Step9: Finding the Optimal Cutoff Point**

Then we plotted the probability graph for the 'Accuracy', 'Sensitivity', and 'Specificity' for different probability values. The intersecting point of the graphs was considered as the optimal probability cutoff point. The cutoff point was found out to be 0.43. Based on the new value we could observe that close to 79% values were rightly predicted by the model. We could also observe the new values of the 'accuracy=79%', 'sensitivity=78%', 'specificity=79%'.

**Step10: Computing the Precision and Recall metrics**

We also found out the Precision and Recall metrics values came out to be 78% and 78% respectively on the train data set. Based on the Precision and Recall tradeoff, we got a cut off value of approximately 0.435.

**Step11: Making Predictions on Test Set**

Then we implemented the learnings to the test model and calculated the conversion probability based on the Recall and Precision metrics and found out the below results:

Accuracy: 78%

Sensitivity: 77%

Specificity: 79%

Precision: 78%

Recall: 77%
